

Single-Nucleotide Polymorphisms (SNPs) in the ORβ-2R-L Gene of French and Spanish Varroa Mite Populations Are Not Directly Linked to Amitraz-Resistant Phenotypes

INTRODUCTION

Amitraz resistance has been linked to **Single-Nucleotide Polymorphisms (SNPs) in the ORβ-2R-L gene**, suggesting a relatively simple genetic mechanism leading to a form of target site resistance. However, as highlighted by Marsky *et al.* (2024) in *Insects*, the resistance phenotype **may involve more complex, multifactorial processes beyond SNPs alone**, warranting deeper genomic and environmental investigation.

Here, we present data:

- Investigating bioassay protocols
- Supporting the hypothesis that SNPs in the varroa mite ORβ-2R-L gene alone can likely not explain the development of amitraz resistance.

These data were collected in an experimental (preliminary) bioassay test in Spain with mites samples from an organic apiary, and a bioassay test in France after reduced field efficacy had been observed on the sampled honey bee colonies.

METHODOLOGY

In autumn 2022, bioassays were conducted in France and Spain to assess amitraz resistance in *Varroa destructor*. In Spain, 12 colonies from an organic apiary near León were divided into three exposure groups (4, 6, and 8 hours) using 3.7×2.2 cm Apivar® strip pieces fixed in Varroa EasyCheck® baskets, with ambient temperature at 21 °C. In France, 200 bees from each of 7 colonies were placed in honey jars with mesh lids and exposed to 1×2 cm Apivar® strip pieces for 6 hours at 25–30 °C. Post-exposure, 52 mites from three of the sampled hives in France (26 survivors, 26 perished) and 50 mites from the five hives in Spain were genotyped to :

- Determine if any Single-Nucleotide Polymorphisms (SNPs) potentially associated with amitraz resistance were present in the ORβ-2R-L gene.
- Investigate correlations between sensitivity towards amitraz exposure and SNP expression in the ORβ-2R-L gene.

RESULTS FROM FRANCE

In the bioassays conducted in France, a total of 49 out of 125 tested varroa mites survived the bioassay exposure to amitraz (See Figure 5). This corresponds to 39% of the tested varroa mites surviving the exposure towards amitraz and therefore being classified as “resistant”. In a later genotypic analysis (Figure 6) of the mites’ ORβ-2R-L gene, we identified 3 distinct mutations in these mites: the mutation described by Hernandez Rodriguez (A260G) (about 36.5% of mites), and two mutations already identified in previous unpublished analyses of French varroa mites: C248T and CA344-345AT. Neither the “American mutation” (T643C), nor the “Spanish mutation” (T868C) was identified within the part of the gene ORβ-2R-L analyzed for these mites. None of the mutations identified here occurred more or less frequently in resistant mites which survived the bioassay exposure towards amitraz.

Figure 5 - France: Bioassay Results

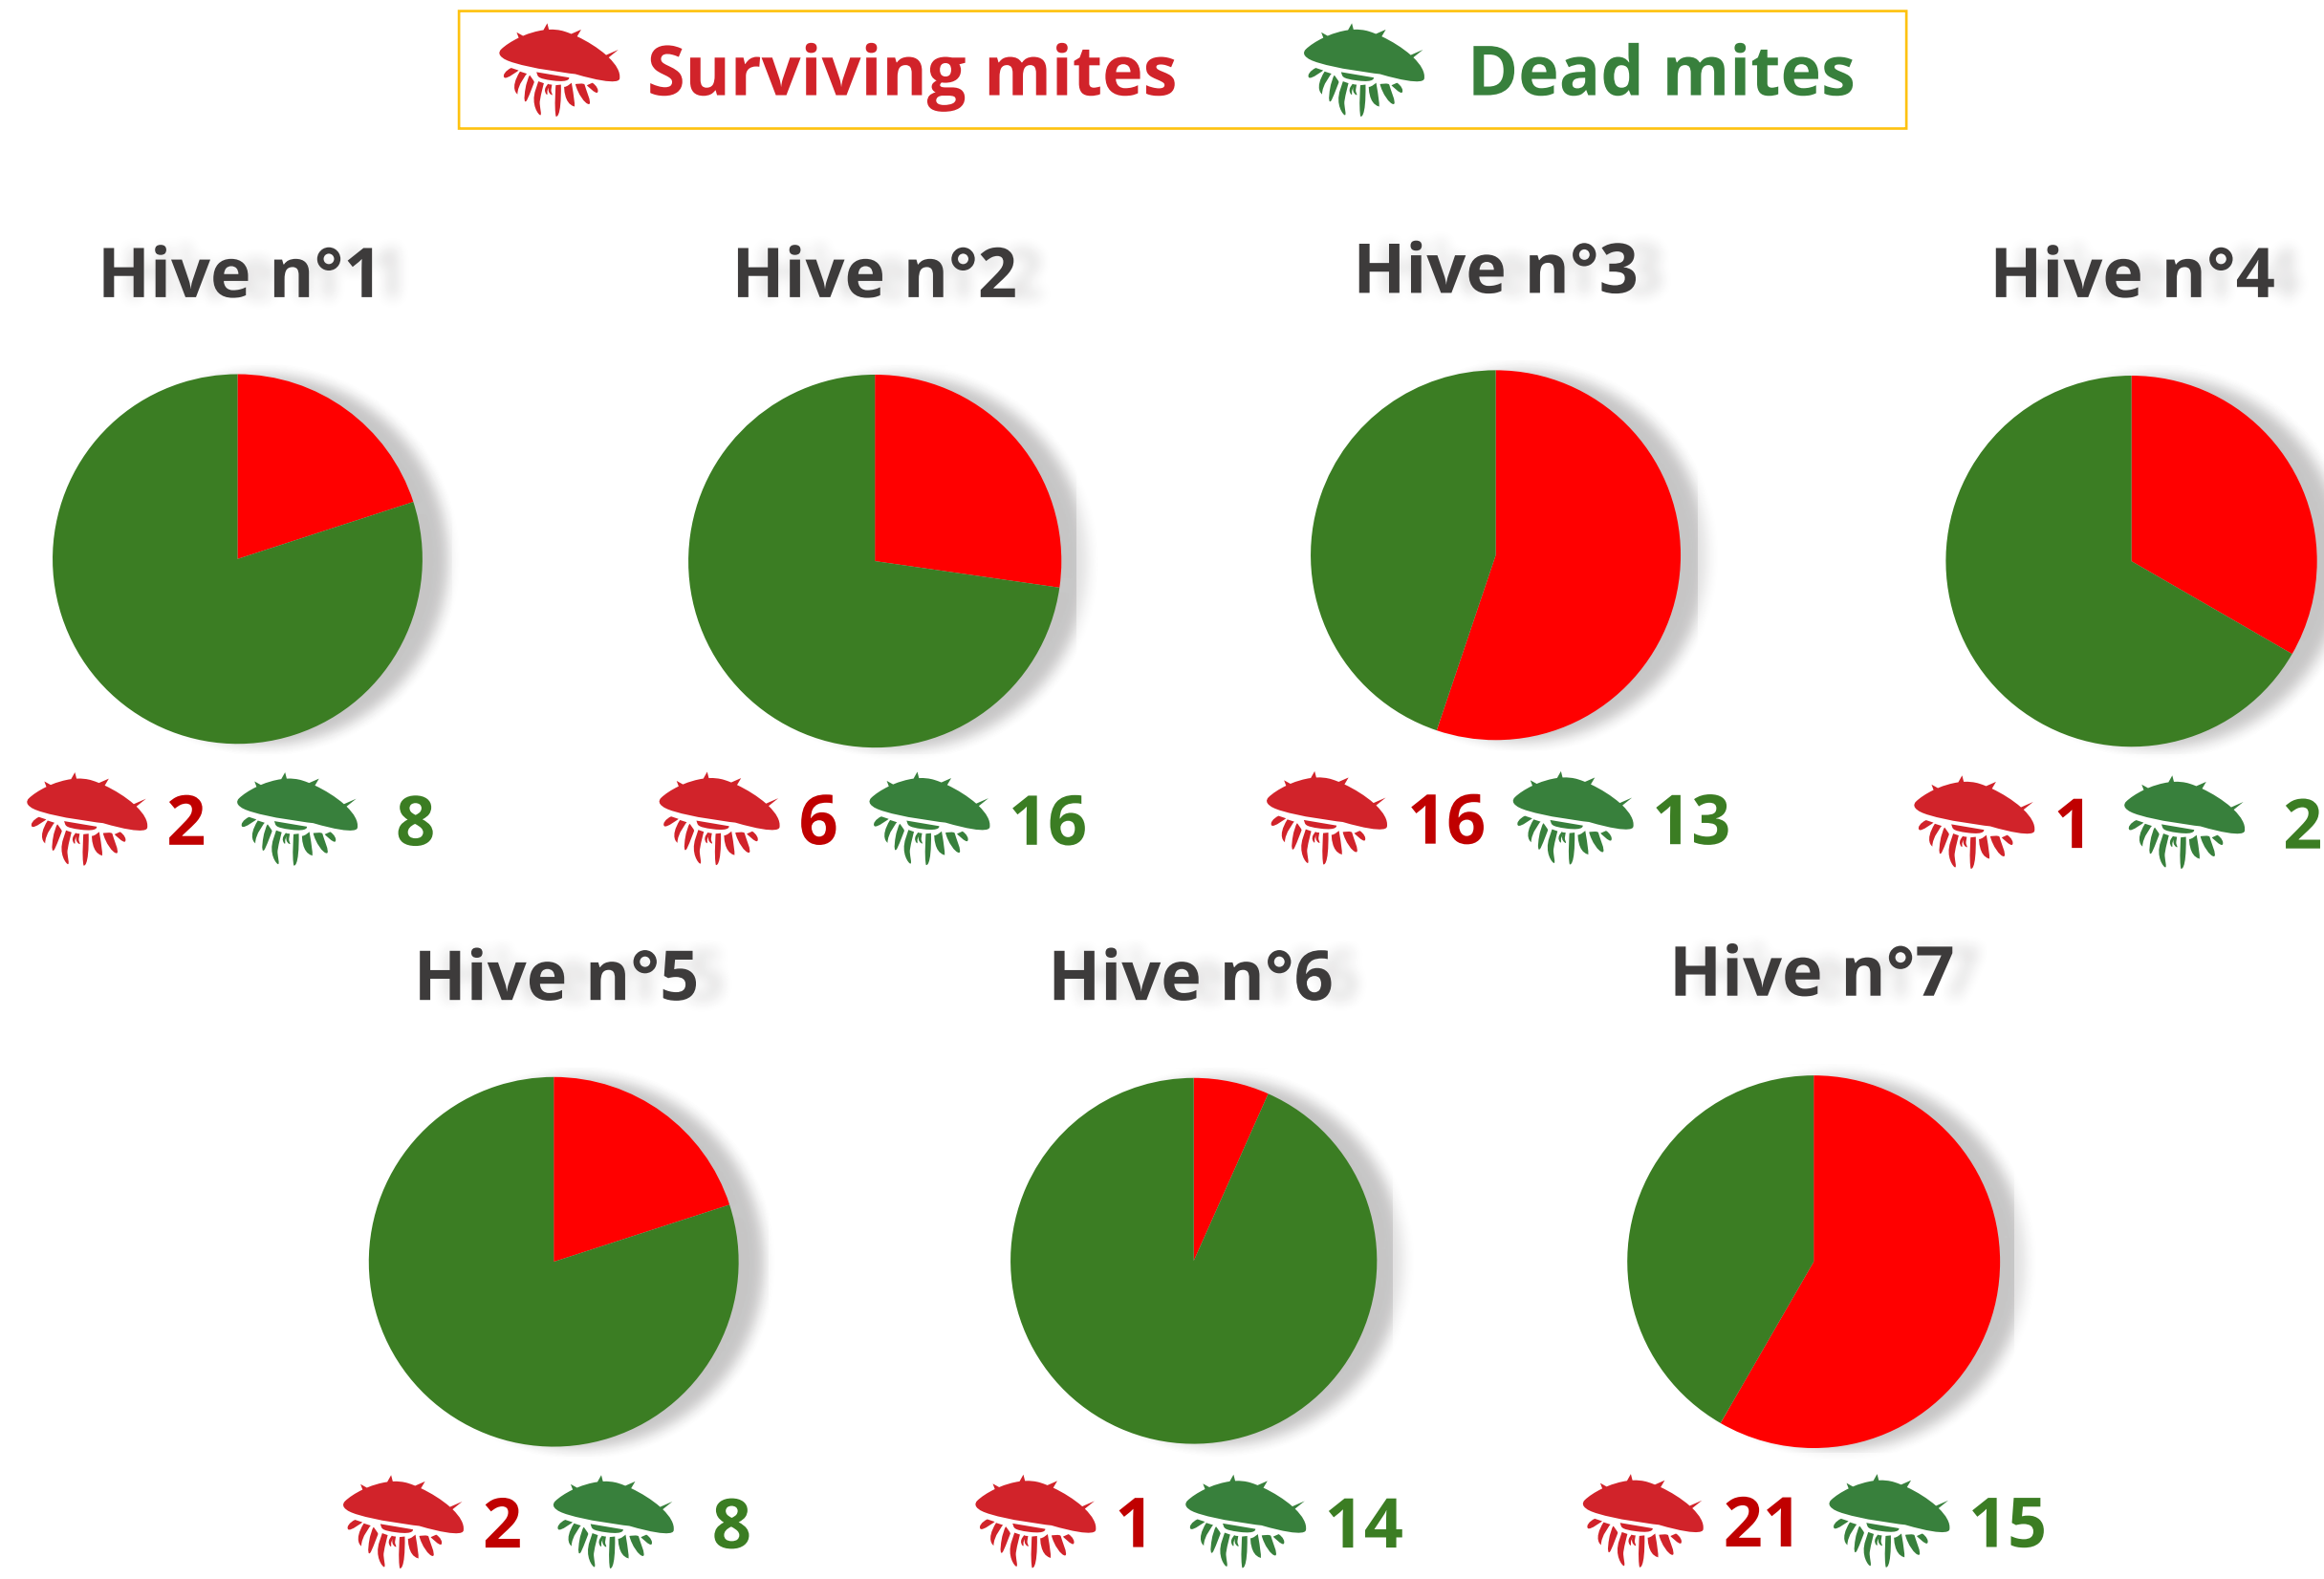

Figure 6 - France: Genotyping Results

Figure 4: 52 mites from France (26 survivors, 26 perished) were genotyped. The Single Nucleotide Polymorphisms (SNPs) first identified in North America, T643C (or Y215H), and Spain (SNP T868C) were not present in these mites - independent of their sensitivity towards amitraz. The mutation N87S (SNP A260G), described by Hernández Rodríguez *et al.* (2022), was present in mites which survived amitraz exposure and mites that perished during the bioassays in the same frequency. Two previously unknown mutations were found at positions C248T and C344A-A345T. The frequency of these mutations did not differ between surviving mites and perished mites.

RESULTS FROM SPAIN

In the bioassays conducted in Spain, a total of 12 out of 204 tested varroa mites from an organic apiary survived the bioassay exposure to amitraz (Figure 3). We identified a previously unknown mutation in the ORβ-2R-L gene of these mites from the León region: the mutation T868C (a substitution of T to C at position 868). None of the mutations previously described in the literature about amitraz resistance in varroa mites (Hernández Rodríguez *et al.* (2022): substitution of A to G at position 260 (A260G) and substitution of T to C at position 643 (T643C)) were detected in these mites (Figure 4). Varroa mites which survived the exposure towards amitraz in the bioassay did not present any specific mutation more frequently compared to the mites which fell during the incubation period (mites from the M1 group).

Figure 3 - Spain: Bioassay Results

Figure 4 - Spain: Genotyping Results

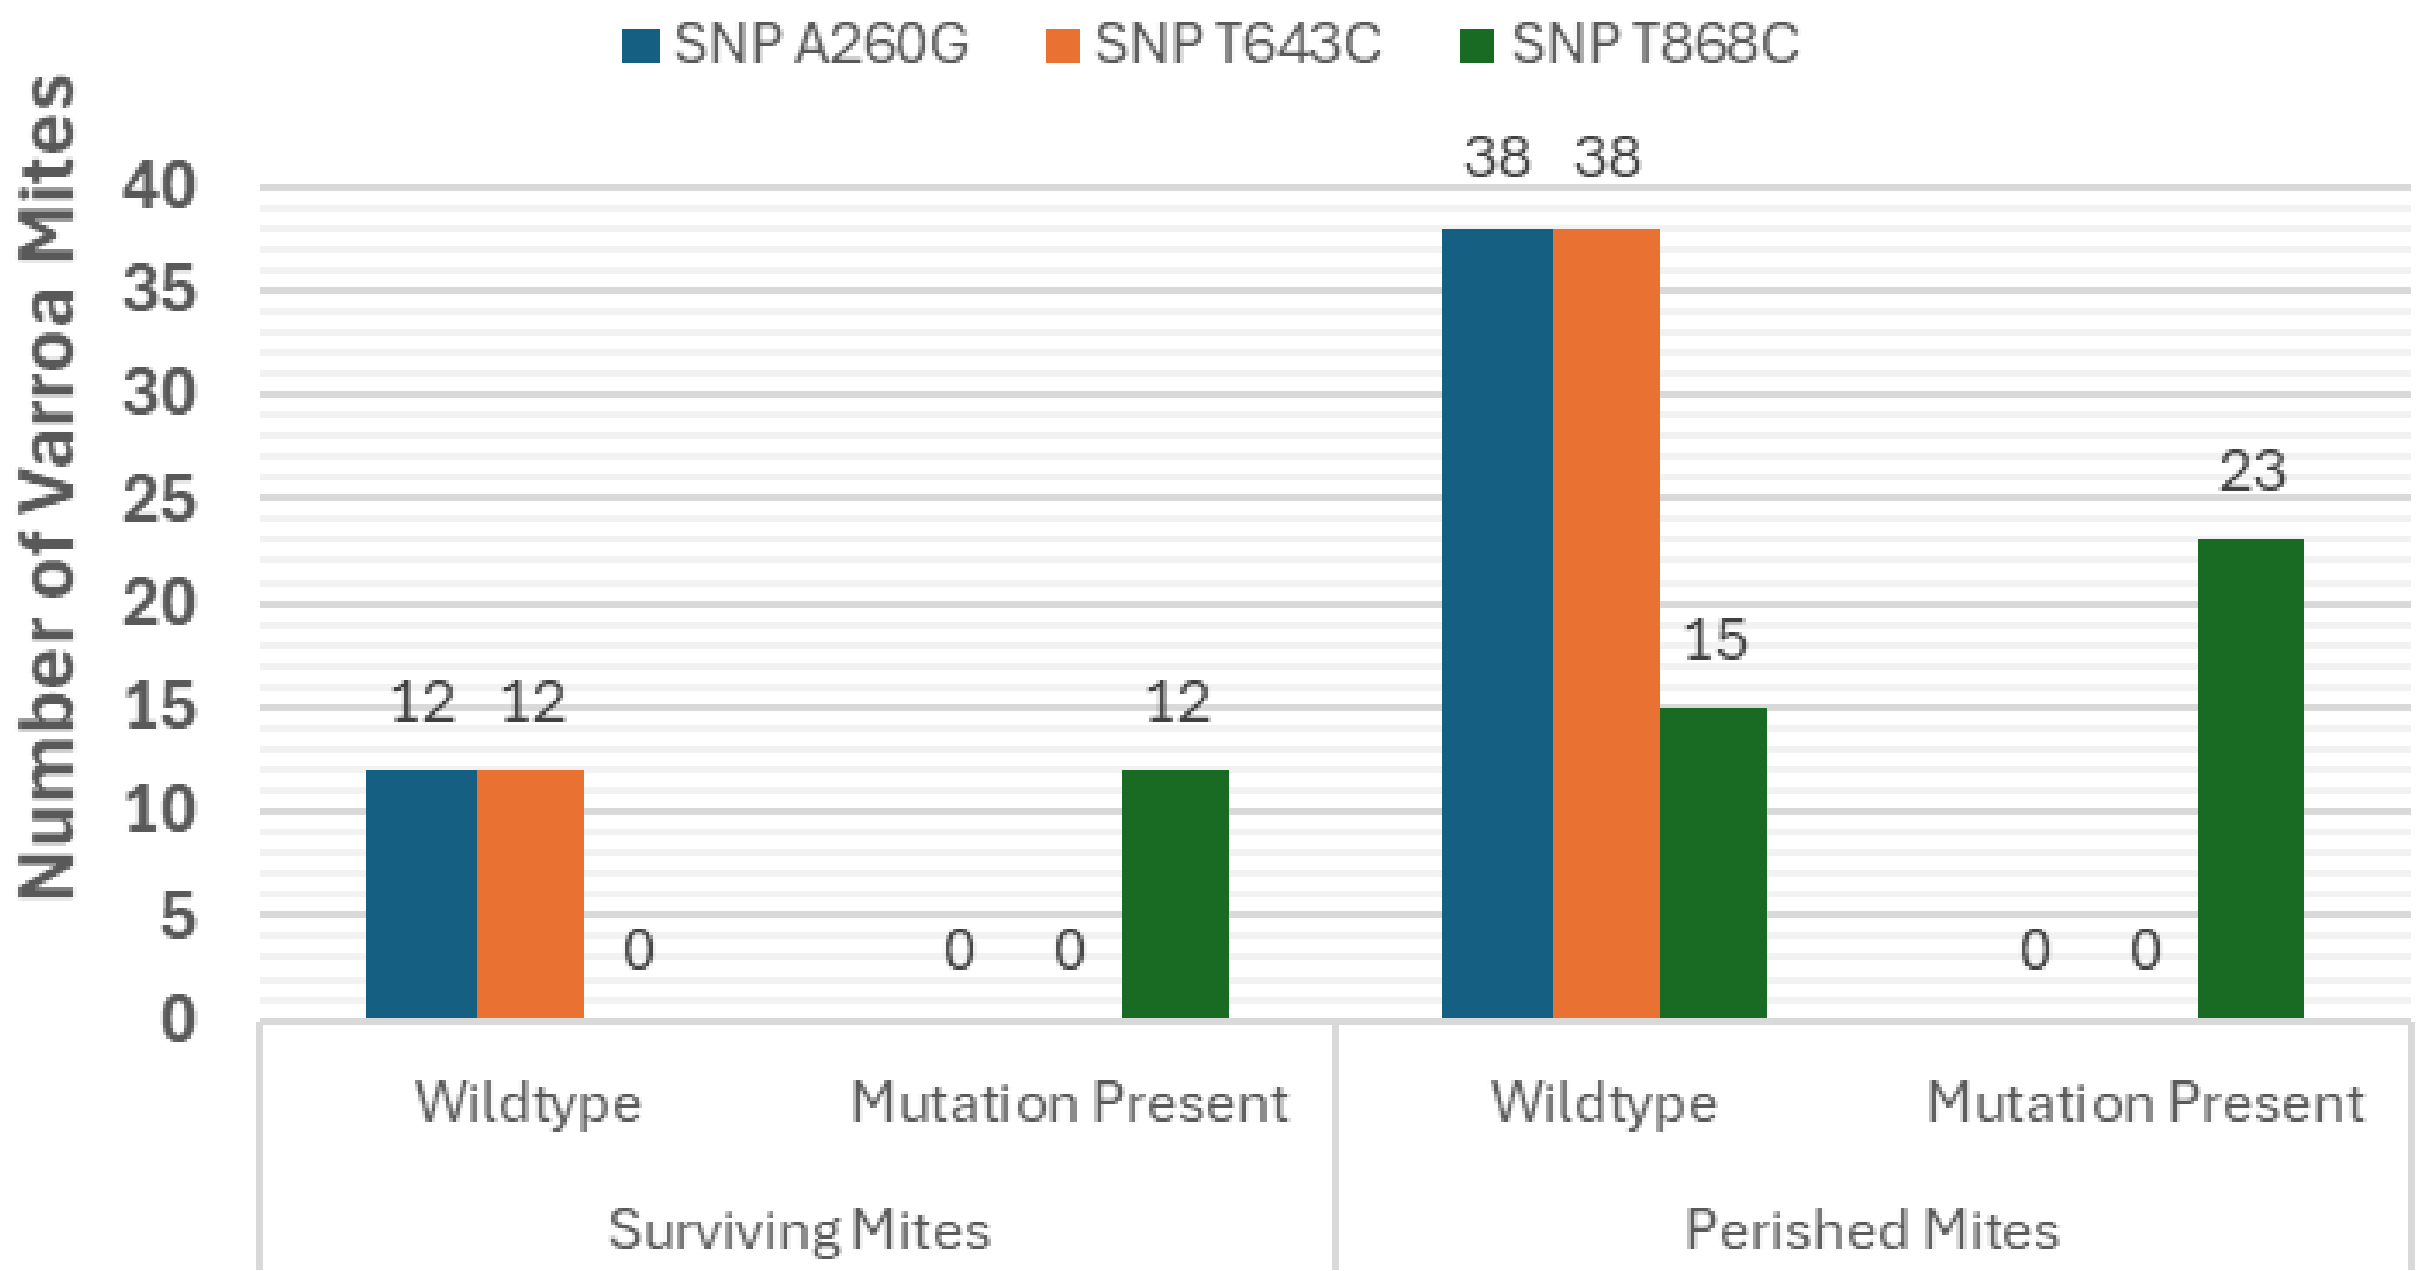

Figure 2: 50 mites from Spain (12 survivors, 38 perished) were genotyped. The Single Nucleotide Polymorphisms (SNPs) first identified in North America (Y215H) and France (Mutation N87S) were not present in these mites - independent of their sensitivity towards amitraz. A previously unknown mutation at location T868C was identified in all of the 12 mites which had previously survived the exposure to amitraz in a bioassay and in 23 of the 38 mites that had perished during the amitraz exposure.

CONCLUSION

- No direct association was found between individual SNPs in the mites’ ORβ-2R-L gene and their phenotype in French and Spanish Varroa mite populations.
- Multiple SNPs were identified, including a novel T868C mutation in Spanish mites from an organic apiary that has not been treated with amitraz for several years.
- None of the mutations was present predominantly in mites phenotypically resistant to amitraz.
- Results indicate that amitraz resistance likely involves complex mechanisms, possibly extending beyond target site resistance.
- Further research is recommended to investigate multifactorial genetic and environmental factors contributing to resistance.
